Background

Hash has been a research question with a long history. The concept of hash is first used in a memo of Hans Peter Luhn in 1953 (Donald K., 2000). After the analysis of the linear probing algorithm by Donald Knuth, the analysis of hashing function becomes famous, and many talented researchers have put efforts into the development of related fields. Nowadays, hash has become not only a well-development research field but also a popular tool that is widely used in programming. Because of its wide utility, we consider it as a focus of our project.

After reading through some related research papers, we decide to look into one of them, titled *Ball and bins: smaller hash families and faster evaluation*. This paper introduces two new constructions that we could guarantee $O(\log n / \log \log n)$ maximum load when throw n balls into n with either a smaller description length or a faster calculation time. Although this is a well-known that with high probability, a $O(\log n / \log \log n)$ -wise independent hash family would guarantee max load of $O(\log n / \log \log n)$. Such $O(\log n / \log \log n)$ -wise independent function can be described by $O(\log^2 n / \log \log n)$ bits, which already yields a dramatic improvement over a truly random function. This paper aims to find an even smaller description length or a faster calculation time of the function while maintaining the guarantee of $O(\log n / \log \log n)$ max load. The special part of this research, specifically about the first construction, is that it constructs an innovative structure of a multi-layer random graph. With such construction of multi-layer graph, each layer is considered as a different hash process with different input and output sizes, which is the number of bins in each layer. Thus, we want to look deep in the first construction of this research and elaborate more details.

Plan

This research paper will contain the following 4 main sections:

Section One is the introduction about the research problem including the reasons that we chose such topic, background information on the topic as well as prior work contributed by other researchers. In the introduction, we will be talking about how truly random hashing functions are impractical in various applications due to the space complexity. We would then be explaining how pair-wise independent hashing functions are introduced with a much more feasible description length and space complexity. Then, we will introduce the construction earlier, which guarantees the same max load while reducing the description length of the function.

In Section Two, there will be two subsections. In Subsection One, we will first prove that the well-known fact, which is with high probability, a $O(\log n / \log \log n)$ -wise independent hash family would guarantee max load of $O(\log n / \log \log n)$. Also we will show the description length of such construction is $O(\log^2 n / \log \log n)$. Following that in Subsection Two, we will list the tools, including some lemmas and theorems as well as their proofs, that our formal proof in section 3 will need. For example, we will be proving the property of a $2k$ -wise δ -dependent random variable, which is an essential step to prove the construction in Section Three.

Section Three will be the essential parts of this research: it will contain the formal introduction of our construction and a formal proof of why this construction works. This section will be split into multiple subsections as well. It will first give a formal description of the construction, and we will be analyzing the construction, essentially explaining the interpretation of such construction. Finally, there will be the most important part of the paper, proving the construction guarantees the description length of hashing function as it claims.

In the end, Section 4 will introduce some extensional uses of this construction. It will also analyze this construction with correspondence to the trade-off it makes in order to obtain the smaller description length of the function.

We plan to finish reading and collecting information about the construction and related tools before 24th July, and we will start writing our research paper right after that. We expect to finish writing the first draft before the end of 3rd Aug and the final draft before the end of 14th Aug.
